

# Meaning Making Through e-Learning

B. Gradinarova<sup>1</sup> and Yuri Gorvits<sup>2</sup>

**Abstract** – Different approaches have been proposed to add more educational value to e-Learning. One of these views proposes modern pedagogical models that better fit the nature of the unique features of technology. A related approach is to embed modern learning and instructional design theory into new communication and interaction channels provided by information and communication technologies such as Internet. This study presents a model for e-Learning illustrated with a specific case study of in-service teacher training in learning with digital media. Intact e-communities were developed through interaction and communication by using Internet services to share meaning, views, and understanding.

**Keywords** – e-Learning, e-communities, learning models.

## I. INTRODUCTION

Diverse approaches have been offered to add more educational value to distance learning programs. Many e-Learning programs emphasize the “e” side, centering on the learning management system used and searching for new tools to “improve” distance learning [3].

Even though these views are necessary we believe that the central focus is somehow missed. Very few studies concerning pedagogical models for distance learning to fit the particular and unique features of Internet are proposed. Most programs follow a chalk and talk way of teaching without paying much attention to innovation by designing new pedagogical models to fit the unique features new media [5],[6]. We can say that this vision is close to the “old wine in new bottle” view.

Other studies identify learning managing systems as key tools that define the learning methodology and strategies. The software framework forces a way of teaching that reduces the flexibility required by active learning methodologies [3],[12]. Many of them end with a model tailored to the technological framework used instead of a software framework built upon the needs and features given by the pedagogical model assumed.

As a result, we can end up with some e-Learning principles that support any course implementation such as: To promote an active role of learners in the construction of knowledge, to promote meaningful learning, to promote broad and deep learning, to develop skills, attitudes and values, to

allow real experiences through real world activities, to promote collaborative learning, to promote a changing role of teachers/tutors as learning facilitators, to involve learners as co-evaluators, to make learners to reflect on what is doing, to use technology to enrich learning, to enhance action on knowledge objects, to solve cognitive conflicts

These principles emerge from underlying theories and models of learning such as constructivism, understanding as thinking, understanding as a network, social interaction, social distribution, situated learning, generalized learning, and self-regulated learning [1],[8].

This study introduces a model for e-Learning that is built upon these principles, models, and theories. We describe the design, implementation, and evaluation of an e-Learning program. Our pedagogical model is illustrated with a pilot implementation with teachers. We highlight the way teachers construct meaning by reflecting on teaching and learning.

## II. DESIGN

We designed a whole e-Learning training program for teachers. We wanted to preserve the academic quality and innovate in the way we deliver education both the technology and model of learning. To do this we followed these steps:

*Technology evaluation:* We selected a learning management system and evaluated the technical requirements

*Team organization:* We created a multidisciplinary team to implement the e-Learning program with engineers, educators, and informatics and education specialists.

*Model of learning:* Once we knew the characteristics of the LMS and content we designed a pedagogical model for e-Learning.

*Pilot testing:* We designed a pilot testing course on methodologies for using information technologies with a reduced number of teachers. We tested the functioning of the LMS and the pedagogical model. We also evaluated diverse materials, working interfaces, learning strategies, type of interactions, and time spent in different section of the course.

*Modeling:* We designed and implemented the structure of the LMS by considering the learning model and the structure of the course program. The content of eight courses was modeled. Most of this content was already in digital format facilitating the process content modeling.

*Online classes:* The students were selected and registered. Then the first week they inspected the platform by following an entrance module. Students also started to virtually communicate and know each other.

*Online modules:* For learners interaction in each course we designed modules with individual and team activities to

design products weekly. They used different interaction tools such as chat and forums to do collective designs and constructions.

**Face-to-face modules:** We designed three out of eight course modules to be delivered face-to-face. They included content that requires more student-facilitator interaction. Each course was delivered in an intensive week with a day topic and collective works.

**Evaluation:** We finally evaluated the courses through questionnaires and opinion polls to get ideas, comments, and suggestions concerning online and face-to-face classes. We also implemented a focus group with professors and tutors of the course program to analyze and discuss the attainment of goals and objectives.

#### A. A model for e-Learning

Our model is based on constructivist principles of learning [8]. We view learning as the process of construction and modification of cognitive structures through learning by experience and collaboration. Each module of the learning cycle is oriented to obtain a contextualized meaningful learning. Learners are required to reflect, apply, criticize, argument, and solve problems and thus allowing them to construct their own representations. We identify five major processes in e-Learning: realizing, approaching, conceptualizing, structuring, and applying.

**Realizing** implies to identify the educational challenge. This process consists of orienting learners in their studies by identifying the problem and making their point of view. They also understand the objectives of the course work proposed and the starting points. They know what they will learn and the reason why the activities are proposed. The learner has to make representations of the expected products and results, and the rationale for doing this. Realizing involves the process of motivating, problem identification, and pre-concept/concept contrasting.

**Approaching** consists of constructing a new learning and point of view by learners guided by a group of professionals that design diverse methodological proposals to fit their cognitive styles. The idea is to produce a cognitive conflict to question the learner's intuitive models and to identify the strengths of the proposed models. It involves the process of reflecting, retention, adapting, exploring, and researching.

**Conceptualizing** involves identifying the concepts and possible conceptual changes when exploring and approaching to the content. It involves the processes of metacognition, representation, and adaptation.

**Structuring** implies to construct meaning through didactic strategies such as synthesis, monitoring, and metacognition. This involves processes such as analysis, synthesis, retention, metacognition, and abstraction.

**Applying** consists of giving the opportunity to students to apply their conceptions to new and different scenarios. It involves evaluation, imaging, adaptation, abstraction, problem solving, contextualizing, and metacognition.

Fig. 1. A model for e-Learning

The virtual interaction triggers a synergic effect on the model by carrying these five processes of knowledge efficiently and thus allowing feedback, confronting ideas, discovering, and collaboration. All these processes are critical in the construction of meaning.

#### B. Training teachers through e-Learning

Our research took place in the Center for teacher development at Moscow Institute for Open Education. There we have implemented an e-Learning experience in order to design and evaluate the proposed methodological learning model. We also wanted to evaluate the learning management system used and to identify main components and strategies to implement an e-Learning course.

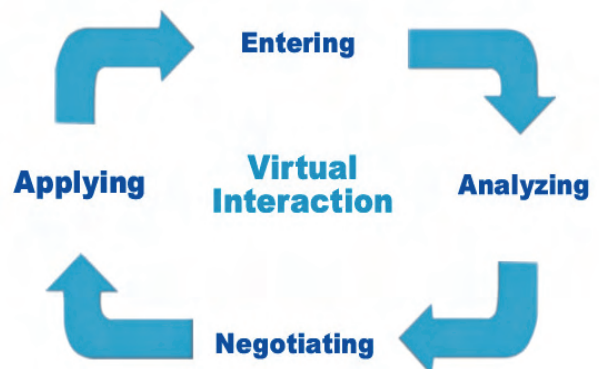

Fig.2. e-Learning cycle

In order to do this we followed five phases: Design, implementation, evaluation, feedback, and redesign. The design of the e-Learning cycle involved processes such as entering to a content unit, analyzing documents, negotiating meaning, and applying what learners have learned through collaborative constructing to end with a group synthesis (see Figure 2).

We have created an interaction virtual space for each content unit to integrate the construction of knowledge around

a topic. Due to the fact that the quality of the interaction among learners was not tacit we implemented an initial strategy to break the initial barriers to communicate and interact. Learners had to introduce themselves to the class by highlighting personal strengths in a playful way and listing their expectancies on the course.

Courses such as the one we are presenting should concentrate in time when teachers work load is not high. The time dedicated by the student to the course is a key to maintain them in the class. The role played by facilitators is very important to foster participation and knowledge construction. The learning management system used can determine the type of activities to be implemented but not necessarily the learning model involved. The follow up strategy is also relevant to the e-Learning experience. Facilitators and administrators should have tools to visualize learner's action within the virtual environment. We also think that the time period dedicated to tutoring and coordinating can determine the quality of the learning experience in online courses. This means time for solving problems, follow up, and to create a working climate to motivate students to actively participate in the learning process.

### III. METHODOLOGICAL STRATEGIES

Each online course was divided in five working units during six weeks with a final evaluation. Units were developed in a week basis and ended with an individual or collective product. The last week was dedicated to prepare and take the final evaluation. Each unit consisted of unit description, objectives, general directions, activities, support materials, web links, and online discussions around each activity and working document.

During each module students were involved in activities such as document synthesis, term glossary, abstracts, graphic representations (schemes, concept maps), collective constructions of documents, comparative charts, and case studies.

Each course consisted of a virtual class section, synchronic communication with the professor responsible of the course and diverse discussion forums to implement activities and documents. The course was in charge of a professor, assisted by a coordinator and a teaching assistant facilitator.

### IV. MEANING MAKING THROUGH VIRTUAL INTERACTION

We based our observation on meaning construction when learners were interacting within the Virtual Dialog Classroom. There two processes can occur: Presenting and Comparing. Presenting involves posing an opinion, comment, information or knowledge. Comparing includes contrasting beliefs and personal known knowledge with other learners by verifying agreements and disagreements.

This implies three other processes: Falsifying, complementing, and discovering. Falsifying implies to assign

falsity or error to a comment or judgments as a result of disappointing with a belief, comment or knowledge idea. Complementing means that we agree with the comment and accept it as a truth but we believe that it is incomplete. Discovering is new knowledge for learning or new ways of viewing a known knowledge. These processes are grouped within the most general process of comparing and can be externalized or just mentally processed without explicating it.

The idea with our study was to go further of just presenting information. We foster discussions where personal known knowledge is proof tested because of the collective interaction ending with a collaborative social knowledge construction. If we wish to evaluate these processes as triggers for meaningful learning we observed a direct relationship between previous knowledge and the quality of the construction of knowledge. Thus the more knowledge a teacher may have on a specific topic the more probability of falsifying. This is very relevant when assigning a role to content and support materials for the Virtual Dialog Classroom.

### V. DISCUSSION

The main goal of this study was to develop a model for e-Learning and test it with a group of teachers by using modern learning theories and principles that better fit e-Learning.

Some of the premises of our design were the enormous potential of collaborative work and virtual interaction in e-Learning as it is mentioned in the literature. However these learning strategies are not tacit and even though they can facilitate learning they can also impede it. To ameliorate this there are some strategies such as teachers sharing their interests in teams and to maintain non formal communication during the course work. This favors confidence among students and group interaction around academic tasks.

One of the key aspects to facilitate collaboration was solving educational problems. Teacher could discuss themes based on their everyday experience by connecting theory and practice, and taking into consideration the teacher's knowledge. A balanced mixture between individual and collaborative strategies is also recommended. e-Learning programs should exploit the unique capabilities of Internet as a communication medium by going further than just student-teacher communication and emphasizing group work among students.

We believe that distance learning programs should exploit the unique features and added value of a powerful medium such as internet. Thus some constructivist theories and principles can be embedded into virtual environments to promote active learning and the construction of meaning.

We have presented an e-Learning model and describe the design, implementation, and evaluation of a training program for school teachers. We analyzed the teacher's construction of knowledge by reflecting on teaching and learning. Through interacting and communicating we have developed electronic communities around pedagogical content. We believe that this

experience reflects a way of knowledge construction from teachers that is not exclusive to e-Learning; rather it can be used in a meaningful way during everyday pedagogical practices in the school.
